1 Growth with GS conditions

1. There is no consistent pattern of growth trends the temperature and water availability across years.
2. The highest growth year (2018) didn't happen in either the warmest or wettest year.
3. The lowest growth was during the driest, but also the warmest season.
4. In terms of season length, we don't observe a clear trend either.
5. The highest growth in 2018 was neither the earliest or latest SOS and EOS or the longest season.
6. The least growth happened in the shortest season, but during the latest SOS unlike what we expected (warmer conditions experienced when SOS is late would lead to increased growth).

2 Ringwidths

I would cut as this does nothing.

3 Model results

1. Warmer thermal seasons increased growth only for one species while the calendar season increased it for three species.
